

NOTIFICATION CONFIGURATION

1. Implementation Steps & Methodology

- Accessed the pre-configured workflow structure inside the **ServiceNow Flow Designer** environment to embed the **Smart Notifications** capability.
- Identified critical transaction touchpoints along the data path—specifically upon initial ticket submission and immediately following a manager's decision (Approval/Rejection).
- Inserted specialized core platform nodes by choosing the **Send Email** action at these tactical junctures to trigger instant communications.
- Configured the communication metadata matrix in the configuration panel: mapped the **To** field recipient dynamically by dragging system data pills (e.g., Trigger -> Leave Request Record -> Employee -> Email and Manager -> Email).
- Drafted the transaction subject line and composed the HTML message template body using a blend of static corporate text and live contextual variables to create intelligent, automated email alerts.
- Conducted end-to-end compilation testing to ensure proper notification delivery, saved the modifications, and executed a live system re-activation.

2. Visual Artifact & Image Analysis

This artifact captures the complete communications architecture mapped out within the Flow Designer canvas, highlighting the successful integration of the system's smart notifications features. The diagram verifies the implementation of four standalone Send Email action blocks positioned at key sequence nodes (Steps 3, 4, 7, and 10). These components are engineered to fire real-time alerts to the submitting employee (confirming receipt or status updates) and to the managing supervisor (providing a direct access link to act upon the pending request), ensuring total transparency throughout the document lifecycle.
